ABSTRACT
The invention disclosed here teaches methods and apparatus for altering the temporal and spatial shape of an optical pulse. The methods correct for the spatial beam deformation caused by the intrinsic DC index gradient in a volume holographic chirped reflective grating (VHCRG). The first set of methods involves a mechanical mean of pre-deforming the VHCRG so that the combination of the deflection caused by the DC index gradient is compensated by the mechanical deformation of the VHCRG. The second set of methods involves compensating the angular deflection caused by the DC index gradient by retracing the diffracted beam back onto itself and by re-diffracting from the same VHCRG. Apparatus for temporally stretching, amplifying and temporally compressing light pulses are disclosed that rely on the methods above.

CORRECTING SPATIAL BEAM DEFORMATION

CROSS-REFERENCE TO RELATED APPLICATIONS

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to a method and apparatus for altering the temporal and spatial shape of an optical pulse. Pulse stretchers based on volume holographic chirped reflection gratings (VHCRG) are used for increasing the temporal length of an optical pulse prior to amplification by an optical amplifier. After amplification, the optical pulse is temporally recompressed by a pulse compressor in order to achieve a short duration pulse. During the process of stretching and recompressing, the spatial shape of the pulse can be distorted by the volume grating. It is desirable to obtain a mean to produce a beam spatial profile that is clean, i.e., free of spatial distortion after the stretching and compression steps by diffraction from a chirped reflecting volume holographic grating.

2. Background Art

FIG. 1 illustrates a state-of-the-art pulse stretcher/compressor pair that produces a high power short pulse. A seed oscillator optical pulse 100 is collimated and directed to a pulse stretcher comprised of two dispersive diffraction gratings 110 and a pair of lenses positioned in between. The diffraction gratings 110 are placed one focal length away from the lenses. The stretched pulse 120 is amplified by an optical amplifier 130, whose output produces a high power stretched pulse 140. The high power long pulse is shortened by a compressor that uses two dispersive diffraction gratings 150. The output of the compressor is a short and intense pulse 160.

The compressor/stretcher based on dispersive grating are bulky due to the small angular dispersion that can be achieved. In contrast, a pulse stretcher/compressor based on non-dispersive volume holographic chirped reflection gratings (VHCRG) is several times smaller. FIG. 2 illustrates the concept. A seed oscillator optical pulse 200 is collimated and directed to a pulse stretcher that is comprised of a VHCRG. The input aperture is typically several square millimeters. The VHCRG can be made out of different thick holographic materials such as photo-thermal glass (PTR) or crystals that have a high peak power damage threshold. Commercial PTR VHCRG typically have several hundreds of MW/cm² damage threshold for 20 ns pulses at 20 Hz repetition rate near 1 μm. FIG. 3 illustrates a damage threshold measurement for commercial PTR volume holographic material.

In PTR holographic glass, a small DC index change arises between the top and bottom of the VHCRG. Absorption of the recording beam during the recording process creates an uneven exposure in the direction of the recording beam throughout the thickness of the material. In holographic photo-thermo refractive glass for example, this exposure change creates a small DC index change of the order of 10⁻⁴.

The DC index change is related to the illumination exposure and thus along the thickness of the sample, the DC index change varies continuously. The DC index gradient affects the propagation of a collimated beam. FIG. 4 illustrates this effect. An undistorted collimated beam 400 with a beam size of the order of the thickness of the VHCRG 410 will be diffracted into beam 420 in the direction of the DC index gradient thus deforming the spatial profile of the incident beam. The output beam profile 430 is shown in FIG. 4. The extent of the angular deflection can be approximated by the following formula: \( \alpha \approx \frac{2\pi a}{\lambda L} \), where a is the deflection angle, \( \frac{2\pi}{\lambda} \) the index of refraction gradient, L the length of the VHCRG and a its average index of refraction. For example, the expected deflection angle in the case of an index gradient of 10⁻⁴ mm, length L of 30 mm and average index of 1.5 yields a deflection angle of 2 mrad. Because the diffracted beam propagates twice the length L of the VHCRG (by reflection), the total deflection angle becomes 4 mrad. After a free space propagation of only 25 cm, a 1 mm diameter pulse diffracted by the VHCRG will be elongated in one direction (the direction of the DC index gradient) by 1 mm. The extent of the oblong spatial beam profile of the diffracted beam 420 matches the above quantitative explanation. Although small, the effect on the spatial beam profile is detrimental for proper amplification of the stretched pulse. It is also detrimental when the recompressed pulse needs to be close to distortion free for applications such as but not limited to thin film photovoltaic scribing, precise machining and ablation.

In order to increase the time delay, while maintaining the same length VHCRG, a double pass configuration with a VHCRG is used. FIG. 5 illustrates the method. A seed oscillator optical pulse 500 is collimated and directed to a pulse stretcher that is comprised of a VHCRG 510 and a flat mirror 520. The angular positioning of the mirror is such that the diffracted beam is reflected and counter propagating. The double pass in the VHCRG 510 increases the time delay by a factor 2 with respect to the single pass configuration illustrated in FIG. 2. However, the beam distortion is amplified by a factor 2 as well. FIG. 6 illustrates this effect. The incident beam is diffracted by the VHCRG 600 and reflected by a flat mirror 610 to produce a counter-propagating beam which is in turn re-diffracted by the VHCRG 600 to produce beam 620. At each diffraction, the deflection increase towards the DC index gradient.

SUMMARY OF THE INVENTION

A method is proposed to correct for the spatial beam deformation caused by the intrinsic DC index gradient in a VHCRG.

The second set of methods involves a mechanical mean of pre-deforming the VHCRG so that the combination of the deflection caused by the DC index gradient is compensated by the mechanical deformation of the VHCRG. The first set of methods involves compensating the angular deflection caused by the DC index gradient by retracing the diffracted beam back onto itself and by re-diffracting from the same VHCRG. Apparatus for temporally stretching, amplifying and temporally compressing light pulses are disclosed that rely on the methods above.
BRIEF DESCRIPTION OF THE DRAWINGS

These and other features, aspects and advantages of the present invention will become better understood with regard to the following description, appended claims and accompanying drawings where:

FIG. 1 (prior art): pulse stretcher/compressor with dispersive diffraction grating.

FIG. 2 (prior art): pulse stretcher/compressor with non-dispersive volume holographic chirped reflective grating (VHCRG).

FIG. 3 (prior art): damage threshold measurement for a volume holographic photo-thermal glass.

FIG. 4 (prior art): illustration of the spatial beam distortion created by a DC gradient index in a photo-thermal volume holographic chirped reflective grating (VHCRG).

FIG. 5 (prior art): pulse stretcher/compressor with non-dispersive volume holographic chirped reflective grating (VHCRG) with double pass arrangement.

FIG. 6 (prior art): details of the double pass arrangement of FIG. 5.

FIG. 7: illustration of a compensated double pass arrangement with VHCRG to provide a distortion free diffracted beam.

FIG. 8: beam profile measurement of the diffracted beam using the method of FIG. 7.

FIG. 9: pulse stretcher/compressor apparatus with non-dispersive volume holographic chirped reflective grating (VHCRG) with double pass arrangement method of FIG. 7.

FIG. 10: illustration of a mechanical mean to pre-distort the VHCRG to provide a distortion free diffracted beam.

FIG. 11: three-dimensional rendition of the illustration in FIG. 10.

FIG. 12: Temperature dependence of the beam profile using the package of FIG. 10.

FIG. 13: detailed measurement of the beam profile at fine temperature increment using the package of FIG. 10.

FIG. 14: Spectral measurement of the VHCRG.

FIG. 15: illustration of an apparatus with uniform beam profile after pulse stretcher/amplification/compressor with two VHCRGs packaged according to FIG. 11.

FIG. 16: illustration of an apparatus with uniform beam profile after pulse stretcher/amplification/compressor with a single VHCRG packaged according to FIG. 11.

DETAILED DESCRIPTION OF THE INVENTION

In the following description of the present invention, reference is made to the accompanying drawings which form a part hereof, and in which a specific embodiment in which the invention may be practiced. It is to be understood that other embodiments may be utilized and structural changes may be made without departing from the scope of the present invention.

FIG. 7 illustrates the method. A right angle mirror or right angle prism 710 replaces the flat mirror found in FIG. 6. The right angle mirror or right angle prism 710 retraces the diffracted beam 720 back onto itself to produce beam 730. During the first diffraction by the VHCRG 700, the beam is no longer collimated in the direction of the DC gradient. However, because the right angle mirror or right angle prism 710 reflects the diffracted beam 720 back onto itself irrespective of the collimation in the direction of the gradient index, the second diffraction re-collimates the beam to provide an undistorted beam profile.

FIG. 8 shows the spatial profile resulting from using the method of FIG. 7. For the compressor, the orientation of the VHCRG is reversed with respect to input beam. The same right angle mirror or prism arrangement is used.

Another embodiment in the invention is the apparatus of FIG. 9 which is uses the embodiment above illustrated in FIG. 7 to provide a spatially clean beam after temporally stretching, amplifying and re-compressing the pulse.

A seed oscillator optical pulse 900 is collimated and directed to a pulse stretcher that is comprised of a VHCRG 910 and a right angle prism or right angle mirror 920. The distortion-free temporally stretched pulse 930 is amplified by an optical amplifier medium 940 which can be, but not restricted to a fiber amplifier or a free space amplifier. The amplified beam 950 is fed into a pulse compressor that is comprised of a VHCRG 960 and a right angle prism or right angle mirror 920. The VHCRG 960 is a stretcher used in reverse i.e. the chirp direction is reversed. A right angle prism or right angle mirror 970 is used respectively for the spatial distortion. This can be realized for example by cutting a VHCRG in two pieces and using one piece as a stretcher and the other as a compressor. The imperfection in the fabrication of the VHCRG stretcher such as the non-linearity of the chirp rate or chirp amplitude can then be corrected by the compressor with near identical imperfections. Beam 980 is a high power short pulse after temporal compression by the VHCRG compressor.

In another embodiment, a VHCRG 1010 is mechanically deformed by applying pressure on one or more points while the edges of the entrance and exit facets of the VHCRG 1010 and 1050 of the VHCRG 1010 respectively are resting on a mount 1020. In general, any mechanical apparatus that provides bending in a direction approximately orthogonal to the incident light direction 1025 and in the direction of the gradient can be used. FIG. 10 shows an example only. A screw 1030 provides an adjustable mean for varying the pressure on the VHCRG and thus the amount of bending. The dimension of the mount 1020 may vary with the cross section and length of the VHCRG 1010. In general, consideration must be adequately taken to provide enough stiffness in the mount to enable bending the VHCRG. Experimentally, the incident distortion-free beam profile 1000 is diffracted by the VHCRG to produce a distortion-free stretched beam 1060. Due to the symmetry of the device, the compressor also produces a distortion-free beam. A three-dimensional rendition of the mount realized with the VHCRG 1100 in a mount 1120. A screw 1110 positioned approximately, but not restricted to, the middle of the mount 1120, can adjust the amount of stress (bending) applied to the VHCRG 1100. The packaged VHCRG of FIG. 11 has been tested a different temperature. The beam quality a three temperature, 11°C (1200), 25°C (1210) and 38°C (1220) is shown respectively in FIG. 12. FIG. 13 shows more detailed measurement of the spatial beam width in two axis at finer temperature increments. The good beam quality of the temporally stretched, compressed beam using the packaged VHCRG of FIG. 11 is also demonstrated in FIG. 14. A lens 1400 collimates the output of a single mode fiber (not shown). The light source is a wide spectral band source (40 nm FWHM). The collimated beam 1410 is diffracted by the packaged VHCRG 1430. The diffracted beam 1440 has a spectral width which is equal to the spectral width of the VHCRG. A beam splitter 1420 picks off the diffracted beam 1440 and redirects it to a lens 1450 which focuses the light into a single mode fiber 1460. The output of the fiber 1460 is fed into a spectrometer 1470. The spectrum 1490 of the diffracted beam matches the spectral bandwidth of the VHCRG. The achieved coupling efficiency of 70% proves that the beam quality is near distortion-free.
Another embodiment in the invention is the apparatus of FIG. 15 which is uses the embodiment above illustrated in FIG. 10-14 to provide a spatially distortion-free beam after temporally stretching, amplifying and temporally re-compressing a pulse. A seed oscillator optical pulse 1500 is collimated and directed to a pulse stretcher that is comprised of a packaged VHCRG 1510 according to embodiments disclosed in FIGS. 10 and 11. The distortion-free temporally stretched pulse 1520 is amplified by an optical amplifier medium 1530 which can be, but not restricted to a fiber amplifier or a free space amplifier. The amplified beam 1540 is fed into a pulse compressor that is comprised of a packaged VHCRG 1550, according to embodiments disclosed in FIGS. 10 and 11. The packaged VHCRG 1550 is a stretcher used in reverse i.e. the chirp direction is reversed with respect to the stretcher. This can be realized for example by cutting a VHCRG in two pieces and using one piece as a stretcher and the other as a compressor. The imperfection in the fabrication of the VHCRG stretcher such as the non-linearity of the chirp rate or chirp amplitude can then be corrected by the compressor with near identical imperfections. Beam 1560 is a high power short pulse after temporal compression by the VHCRG compressor.

In yet another embodiment, a seed oscillator optical pulse 1600 is collimated and directed to a pulse stretcher that is comprised of a packaged VHCRG 1610 according to embodiments disclosed in FIGS. 10 and 11. The distortion-free temporally stretched pulse 1620 is amplified by an optical amplifier medium 1630 which can be, but not restricted to a fiber amplifier or a free space amplifier. The amplified beam 1640 is directed by a set of mirrors towards the opposite facet of the same VHCRG 1610. The temporally stretched beam 1640 is temporally compressed by the VHCRG 1610 to produce a high power short pulse beam 1650.

In all the embodiments above, the optical radiation whose temporal and spatial profile is altered can be produced, but not limited to, a semiconductor laser, a solid state laser, a fiber laser in the range of 260 nm to 2.5 micrometers.

What is claimed is:

1. A method for correcting spatial beam deformation comprising:
   - resting a volume holographic chirped reflective grating on a mount;
   - receiving an optical beam propagated in free space and directed at the volume holographic chirped reflective grating, the optical beam being temporally stretched, the volume holographic chirped reflective grating causing spatial beam deformation of the optical beam; and
   - applying mechanical pressure to the mounted volume holographic chirped reflective grating, the mechanical pressure being applied approximately from a middle of the mount and causing a bending of the volume holographic chirped reflective grating, the bending being in a direction approximately orthogonal to the optical beam and correcting the spatial beam deformation of the optical beam.

2. The method of claim 1, further comprising adjusting the mechanical pressure applied to the mounted volume holographic chirped reflective grating, the adjustment of the mechanical pressure corresponding to an amount of bending.

3. The method of claim 1, further comprising testing the volume holographic chirped reflective grating by measuring quality of the optical beam diffracted by the volume holographic chirped reflective grating over a range of temperatures.

4. The method of claim 1, wherein the volume holographic chirped grating comprises photo thermal glass and the mechanical pressure is applied using thermal binding.

5. An apparatus for correcting spatial beam deformation comprising:
   - a mount for holding a volume holographic chirped reflective grating, the volume holographic chirped reflective grating having an entrance facet and an exit facet, the entrance and exit facets each having an edge, the edges of the entrance and exit facets resting on the mount, wherein an optical beam propagated in free space and directed at the volume holographic chirped reflective grating is temporally stretched and wherein the volume holographic chirped reflective grating is determined to cause spatial beam deformation of the optical beam; and
   - a structure, the structure applying mechanical pressure to the mounted volume holographic chirped reflective grating, the mechanical pressure causing a bending of the volume holographic chirped reflective grating such that the bending is in a direction approximately orthogonal to the optical beam and corrects the spatial beam deformation of the optical beam.

6. The apparatus of claim 5, wherein the structure applying mechanical pressure is further used to adjust the mechanical pressure applied to the mounted volume holographic chirped grating, the adjustment of the mechanical pressure corresponding to an amount of bending.

7. The apparatus of claim 5, further comprising:
   - an amplifier, the amplifier increasing power of the corrected optical beam to produce an amplified optical beam; and
   - a compressor, the compressor temporally compressing the amplified optical beam, the compressor including a second volume holographic chirped reflective grating under a same amount of mechanical pressure as the volume holographic chirped reflective grating.

8. The apparatus of claim 7, wherein the second volume holographic chirped reflective grating is fabricated from a common piece as the volume holographic chirped reflective grating.
